Asset Pricing: Extensions

State contingent claims

- Some assets pay out only in particular states of the world
  - e.g. insurance contracts
- Standard asset pricing formulas apply to those assets.
- It just adds notation...

State contingent claims

- We start from the Lucas fruit tree model.
- In addition to stocks and bonds, households can purchase assets that pay out in exactly one state of the world.
  - Arrow securities
- Their role in theory:
  - given a sufficiently rich set of Arrow securities, we can replicate any asset
  - can set up a model with all possible insurance opportunities (complete markets)

Notation

- quantity purchased of asset that pays out in state d': $y'(d'|d)$.
    - for convenience just write $y(d')$
- price of that asset: $q(d'|d)$.

Household

States: all assets held, $k, b,$ and all $y(d)$.

- call that s

Choices: $b', k', y(d')$ for all d'.

Dynamic Program:

$$V(s,d) = \max_{c,k',b',y(d')} u(c) + \beta EV(s', d')$$

subject to

$$Rb + (p+d)k + y(d) = c + b' + pk' + \sum_{d'} q(d'|d) \ y'(d')$$

Note: only the y matching the realized value of d pays out.

First-order conditions for state contingent claims

$$u'(c)\,q\left(d'|d\right) = \beta\,\Pr\left(d'|d\right)V_{y(d')}\left(s',d'\right)$$

Envelope:

$$\begin{aligned} V_{y(d)}(s,d) &= u'(c) \qquad (1) \\ V_{y(d)}\left(s,\hat{d}\right) &= 0, \;\; \hat{d} \neq d \qquad (2) \end{aligned}$$

Note: only the y matching the realized value d has value.

Euler equation

$$u'\left(c[s,d]\right) q\left(d'|d\right) = \beta \Pr\left(d'|d\right) u'\left(c[s',d']\right) \tag{3}$$

In more standard form:

$$1 = \Pr\left(d'|d\right) \frac{\beta u'(c[s',d'])}{u'\left(c[s,d]\right)} \frac{1}{q\left(d'|d\right)} \tag{4}$$

where the rate of return on the state contingent claim is $1/q$.

Lucas Equation

We could have written this down without any derivation by just applying the Lucas asset pricing equation:

$$1 = \mathbb{E}\{MRS_{t+1}\frac{1}{q(d',d)}\}$$

Special feature of Arrow securities: Only one term in the $\mathbb{E}$ is non-zero.

Adding Bonds

Adding Bonds

- We add bonds of different maturities to the Lucas model
- There are bonds for maturities $i = 1, ..., n$.
- A bond of maturity i pays one unit of consumption i periods from now. Its price is $p_{t,i}$.
- These are discount bonds which do not pay interest.

Household Problem

- Controls in period t:
    - s_{t+1}: share purchases
    - $b_{t+1,i}$ for $i = 0, ..., n-1$: bond purchases
    - c_t: consumption
- State variables: s_t, $b_{t,i}$ for $i = 0, ..., n-1$
- Budget constraint:

Dynamic Program

$$V(s, b_0, ..., b_{n-1}; d) = \max u(c) + \mathbb{E}\beta V(s', b'_0, ..., b'_{n-1}; d')$$

subject to the budget constraint

First-order conditions:

Standard for the stocks, which yields the usual asset pricing equation.

For the bond:

$$b'_i : u'(c) p_{i+1} = \beta \mathbb{E} V_{b_i}(.') \tag{5}$$

Envelope:

$$V_{b_i} = u'(c) p_i \tag{6}$$

Euler:

$$u'(c) p_{i+1} = \beta \mathbb{E} u'(c') p'_i$$

Bond prices

Solve this by backward induction:

$$p_0 = 1 \tag{7}$$

Sub that into the Euler equation and iterate to find

$$p_{t,i} = \beta^i \mathbb{E} \frac{u'(c_{t+i})}{u'(c_t)} \tag{8}$$

with $c_t = d_t$.

Bond prices

These are actually the standard Lucas asset pricing equations

The per period return on the bond is $1+r_{t,i} = (1/p_{t,i})^{1/i}$

Therefore:

$$u'(c_t) = \beta^i \mathbb{E} u'(c_{t+i})(1+r_{t,i})^i \tag{9}$$

$r_{t,i}$ is not stochastic and $Eu'(c_{t+i}) = Eu'(d_{t+i})$ does not depend on the current state d.

Yield curve

- Yield: $1 + r_{t,i} = [u'(c_t) / Eu'(c_{t+i})]^{1/i} / \beta$
- With iid dividends: high consumption implies low yields for all maturities
- When c is above average $(u'(c_t) < \mathbb{E}u'(c_{t+i}))$, the yield curve is downward sloping
- This is consistent with data (the yield curve "predicts" slow growth).
