# Overlapping Generations Model

Prof. Lutz Hendricks

Econ720

August 23, 2016

#### Introduction

Two approaches for modeling the household sector

- households live forever (infinite horizon) tractable
- households live for finite number of periods (overlapping generations)
   can talk about questions where demographics matter

## **OLG** Applications

Fiscal policy analysis

often models where households live many periods

Economic growth

Business cycles (when stochastic)

Many others...

#### What we do in this section

- ► How to set up and solve an OLG model
- ► Show that the world is **not efficient**: households may save too much.
- "Social security" can prevent overaccumulation
- We can make households "infinitely lived" by adding altruistic bequests.

## What we don't do in this section

- ▶ We sidestep some technical issues:
  - why is there a representative household?
  - why is there a representative firm?
- ▶ We come back to those later.

An OLG Model Without Firms

## Steps

#### We go through the standard steps:

- 1. Describe the economy: demographics, endowments, preferences, technologies, markets
- 2. Solve each agent's problem
- 3. Market clearing
- 4. Competitive equilibrium

# **Demographics**

At each date a cohort of size

$$N_t = N_0(1+n)^t$$

is born.

- Each person lives for two periods.
- ▶ Therefore, at each date there are  $N_t$  young and  $N_{t-1}$  old households.

# Endowments, Preferences

- Endowments
  - ► Young households receive endowments w<sub>t</sub>.
- ▶ Preferences:  $u(c_t^y) + \beta u(c_{t+1}^o)$ .

## Technology

- Endowments can be stored.
- ▶ Storing  $s_t$  today yields  $f(s_t)$  tomorrow.
- Resource constraint:

$$N_t c_t^y + N_{t-1} c_t^o + N_t s_t = N_t w_t + N_{t-1} f(s_{t-1})$$
 (1)

#### Resource constraints

Technological constraints that describe the set of feasible choices.

Often identical to market clearing conditions.

#### Markets

Goods are traded in spot markets.

Households can issue one period bonds with interest rate  $r_{t+1}$ .

We are done with the description of the environment.

Next step: solve the household problem.

# A Missing Market

Even though there is a bond market, **intergenerational** borrowing and lending is not possible.

The reason: the young at t cannot borrow from the old because the old won't be around at t+1 to have their loans repaid.

▶ If households live for more periods, the problem becomes weaker, but does not go away.

An asset that stays around forever solves this problem

e.g., money, land, shares

## Household Problem

► The budget constraints are

$$w_t = c_t^y + s_{t+1} + b_{t+1}$$
  
$$c_{t+1}^o = f(s_{t+1}) + b_{t+1}(1 + r_{t+1})$$

Lifetime budget constraint:

$$w_t - c_t^y - s_{t+1} = [c_{t+1}^o - f(s_{t+1})]/[1 + r_{t+1}]$$

# Lagrangian

$$\Gamma = u(c_t^y) + \beta u(c_{t+1}^o) + \lambda_t \{ [w_t - c_t^y - s_{t+1}] - [c_{t+1}^o - f(s_{t+1})] / [1 + r_{t+1}] \}$$

FOCs:

$$u'(c_t^y) = \lambda_t$$
  
 $\beta u'(c_{t+1}^o) = \lambda_t/(1+r_{t+1})$   
 $f'(s_{t+1}) = 1+r_{t+1}$ 

## Euler equation

$$u'(c_t^y) = \beta (1 + r_{t+1}) u'(c_{t+1}^o)$$

#### Interpretation:

Give up 1 unit of consumption when young and buy a bond.

Marginal cost:  $u'(c_t^y)$ 

Marginal benefit:

 $(1+r_{t+1})$  units of consumption when old

valued at  $\beta u'\left(c_{t+1}^o\right)$ 

#### Household Solution

A vector  $(c_t^y, c_{t+1}^o, s_{t+1}, b_{t+1})$  which satisfies

- ▶ 2 FOCs (an EE and the foc for s)
- 2 budget constraints.

This is (unsurprisingly) the same as in the two-period model.

## Equilibrium

A CE is an allocation  $\{c_t^y, c_t^o, s_t, b_t\}$  and a price system  $\{r_t\}$  that satisfy:

- 4 household conditions
- ▶ bond market clearing:  $b_t = 0$ ;
- goods market clearing (same as resource constraint):

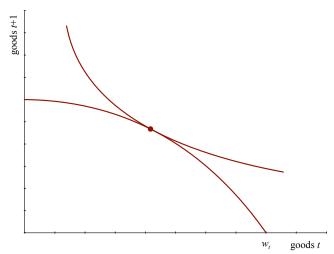

$$N_t c_t^y + N_{t-1} c_t^o + N_t s_t = N_t w_t + N_{t-1} f(s_{t-1})$$
 (2)

We are done with the definition of equilibrium.

Next step: characterize equilibrium.

## Characterization

There is no trade in equilibrium  $(b_t = 0)$ 

# A Production Economy

# A Production Economy

- ► The model is modified by adding firms who rent capital and labor from households.
- ▶ The endowment w is now interpreted as labor earnings.
- Households supply one unit of labor inelastically to firms when young.
- Capital depreciates at rate  $\delta$ .

#### Model Elements

- Unchanged: demographics, preferences
- Endowments:
  - ▶ at t = 0 each old household owns  $k_0$  units of capital
  - each young has 1 unit of work time
- Technology

$$F(K_t, L_t) + (1 - \delta)K_t = C_t + K_{t+1}$$
(3)

- constant returns to scale
- Inada conditions
- Markets:
  - ▶ goods (numeraire), capital rental (q), labor rental (w)

#### Notes

## Representative household

- All households are the same.
- So we talk as if there were only 1 household, who behaves competitively.

## The household owns everything

- The firm rents capital from the household in each period
- That makes the firms' problem static (easy)
- It is usually convenient to pack all dynamic decisions into 1 agent
- In this model, who owns the capital makes no difference why not?

## Households

Budget constraints:

$$w_{t} = c_{t}^{y} + s_{t+1} + b_{t+1}$$

$$c_{t+1}^{o} = e^{o} + (s_{t+1} + b_{t+1})(1 + r_{t+1})$$

- $ightharpoonup e^o$ : any other income received when old (currently 0)
- ► There are no profits b/c the technology has constant returns to scale.

## Lifetime budget constraint

► Combine the 2 budget constraints:

$$w_t - c_t^y = (c_{t+1}^o - e^o) / [1 + r_{t+1}]$$

or

$$W_t = w_t + \frac{e^o}{1 + r_{t+1}} = c_t^y + \frac{c_{t+1}^o}{1 + r_{t+1}}$$
 (4)

 $ightharpoonup W_t$ : present value of lifetime earnings

## Permanent Income Hypothesis

The lifetime budget constraint only depends on  $W_t$ , not on timing of income over life.

Therefore, the optimal consumption path only depends on  $W_t$ .

This is a somewhat general implication that has been tested many times.

## A recent example:

 Hsieh, C. T. (2003). Do consumers react to anticipated income changes? Evidence from the Alaska permanent fund. American Economic Review, 397-405. [Nice example of using a natural experiment to test a theory.]

Overall, the evidence seems favorable.

## Lagrangian

$$\Gamma = u(c_t^y) + \beta u(c_{t+1}^o) + \lambda \{W_t - c_t^y - c_{t+1}^o / [1 + r_{t+1}] \}$$

FOCs:

$$u'(c_t^y) = \lambda$$
  
$$\beta u'(c_{t+1}^o) = \lambda/(1+r_{t+1})$$

## Households

Euler:

$$u'(c_t^y) = \beta(1 + r_{t+1})u'(c_{t+1}^o)$$

Solution: A vector  $(c_t^y, c_{t+1}^o, s_{t+1}, b_{t+1})$  that satisfies 2 budget constraints and 1 EE.

We lack one equation! Why?

# Graph: Household Solution

## Assuming:

- ▶ log utility:  $c_{t+1}^o/c_t^y = \beta(1+r_{t+1})$
- many periods

#### **Firms**

Firms maximize current period profits taking factor prices (q, w) as given.

$$\max F(K,L) - wL - qK$$

FOCs:

$$q = F_K(K,L)$$
  
$$w = F_L(K,L)$$

#### Firms: Intensive form

It is almost always convenient to write the production function in intensive form:

$$F(K,L) = LF(K/L,1)$$
$$= Lf(k^F)$$

where  $k^F = K/L$  and

$$f(k^F) = F(k^F, 1)$$

This, of course, requires constant returns to scale.

## Firms: Intensive form

Now the factor prices are

$$F_K = Lf'(k^F)(1/L)$$

and

$$F_L = f(k^F) + Lf'(k^F)(-K/L^2)$$
  
=  $f(k^F) - f'(k^F)k^F$ 

Therefore:

$$q = f'(k^F)$$
  
$$w = f(k^F) - k^F f'(k^F)$$

Important: q is the rental price of capital, which differs from the interest rate r.

The solution to the firm's problem is a pair (K,L) so that the 2 FOCs hold.

# Market clearing

Capital rental:  $K_{t+1} = N_t s_{t+1}$ 

Labor rental:  $L_t = N_t$ 

Bonds:  $b_t = 0$ 

Goods: resource constraint

# Competitive Equilibrium

```
An allocation: (c_t^y, c_t^o, s_t, b_t, K_t, L_t)
Prices: (q_t, r_t, w_t)
```

That satisfy:

- the household EE and budget constraints (3 equations)
- the firm's FOCs (2 equations)
- the market clearing conditions (4 equations)

We have 9 objects and 9 equations – one is missing.

We need an accounting identity linking r and q:

- ▶ The household receives  $1 + r_{t+1} = q_{t+1} + 1 \delta$  per unit of capital.
- ▶ Therefore,  $r = q \delta$ .
